Isikeli Valemei ACP-EU Development Minerals
Programme Phase 2 Country Coordinator

Why is a guideline required?

There is increasing evidence of environmental problems associated with rivers and streams with gravel and sand extraction.

Extraction of river gravel and sand has potential for serious impact on many aspects of the environment.

Legislative control on river gravel and sand mining are administered by a number of government regulators with little provision to address the cumulative effect of multiple operations on any one river or stream.

Management decisions must be based on the principle of sustainable development not only for gravel and sand resources but also for communities that use rivers and streams and the values that come with healthy rivers and streams.

It is also recognised that it is an economically important resource being the principal source for the Transport (roads) and construction industries

Issues related river and stream mining

Environmental Impacts

Areas of National diversity here important to ensure no mining activity in rivers that conflict with the aims of preserving biodiversity, wilderness areas, recreational and rural areas where rural communities depend on rivers and streams for subsistence resources

River geomorphology- increased erosion, channel change and re-alignment, increased sedimentation, changes in flood size magnitude and frequency , bridge infrastructure impacts, dwelling loss.

River bed and bank erosion – source and sink processes if a net loss due to mining occurs the river responds with erosion of bed, banks or both.

Excavation below riverbed level may lead to river bank erosion.

Cumulative impacts of more than one operator on any one river compound impacts and needs to be controlled.

Estuaries and tidal rivers and streams – turbidity , saline intrusion , restricted navigation.

Groundwater quality and quantity - excessive river mining can result in flood plain aquifer impacts with reduced groundwater recharge rates.

Siltation and turbidity release of fines during mining result in higher turbidity issues with navigation and negate the use of the river by rural communities.

Water Quality an increase in suspended solids and siltation have major impact on urban water supply by increasing costs for treatment and filtration In particular river and stream extraction in watershed reserves for urban center supply. Changes in river flow with over extraction can result in algae growth due to reduced flow velocities.

Vegetation and Riparian habitats loss of riparian habitats on flood plains, construction of road access to rivers, trees falling into rivers deflecting water flows and causing or aggravating erosional problems.

Pollution release of hydrocarbons products from mechanical diggers, trucks etc into the waterways.

OBJECTIVES OF SUCH A GUIDELINE

To ensure that extraction of gravel and sand from the States rivers and streams is done on a sustainable basis.

To ensure that the management of the extraction minimises any detrimental effects on the river and stream environments and fundamentally protects other rivers users and values.

Before

After

Images Credit MRD

That the river and stream mining guideline is consistent with the aims of other Government policies and initiatives. For example:

National Biodiversity Strategy and Action Plan for Fiji 2020-2025

Strategic Area SUD4: Reducing major threats to inland waters (watershed, streams, rivers and lakes) such as dredging, floods, gravel extraction, mining, agriculture, deforestation, tourism, sugar, manufacturing, waste management.

Objective SUD4: Establish locally managed areas protected areas and/or Ramsar sites, at priority catchments, wetlands and key biodiversity areas and **strengthen EIAs** for all forms of development activity in inland waters.

Strategic Area SUD5: Reduce major threats to Fiji's coastal ecosystems such as reclamation, unsustainable tourism development, river dredging and pollution.

Areas the GUIDELINE sets out to address

The EIA report: In the UNDP Development mineral report study it was found that out of 58 EIA reports reviewed only one addressed the issue of sustainability with respect to river gravel mining

Typically the EIA's are generic often reflect a lot of cut and paste-material with little relevance to the core purpose of providing data that can fundamentally be used for monitoring upstream and downstream effects of river gravel and sand mining activities and long term change.

Some of the short comings are:

- Reports lack technical detail such as maps that detail the resource, are not to scale suitable for evaluation and do not record existing geomorphology and physical parameters such as river cross sections, depth as in bathymetry, aerial extent of gravel bars and sheets, river bed and river bank conditions.
- Do not recognize Infrastructure impacts or the potential impact off.
- Assessment of existing gravel deposits and river stability, flood plain channel re-alignment, increased sedimentation in estuarine zones.
- Accurate maps would prevent boundary problems, with cultural sensitives of LOU's and overlaps with multiple licenses on a single river system
- Limiting the number of extractors on a river system. Reports do not recognise that multiple licenses users on a single river, stream can compound problems and evaluation of the impacts perceived to have been caused by the extraction.
- Little or no assessment on bed load transport rates

The ability to monitor ; For the GUIDELINE to include such measures and strategies implies an associated COST to implement - and to who? - the State, Private sector or combination of both or paid through license process?

A River Gravel and Sand Extraction Guideline 2021

- 
- A photograph of a river with a wide, sandy bank on the right side. The water is dark blue and calm. In the background, there is a dense line of green trees and foliage. Two people are visible in the water, swimming or wading. The text of the table of contents is overlaid on the left side of the image.

Aggregate production 2017

| Product | Volume (m³) | Average price of various products per m³ (FJ\$) | Estimated Value of Output (FJ\$) |
|------------------------------------------------|-------------|-------------------------------------------------|----------------------------------|
| Various products (river extraction) | 2,300,000 | FJ\$75 | FJ\$172.5M |
| Various products (hard rock quarries) | 1,244,400 | \$100 | FJ\$124.4M |
| Various products (sand and soft rock quarries) | 40,000 | \$35 | FJ\$1.4M |
| Gross Output | | | FJ\$298.3M |

Current river mining licenses and activity 2020-2021

River Mining Inspections 2019

River Mining Inspections 2020

Social Impacts

- Unsafe boat transport on river
- Depleted fisheries
- Sedimentation
- Contaminated drinking water
- Bathing/cleaning- hygiene and health issues
- Erosion and loss of land/agriculture
- Issues with royalty payments
- Lack of environmental compliance
- Lack of consultation- licensing and lease
- Resource ownership confusion- native vs state.
- Unclear process and regulatory framework

represents river position in
2004

Bridge

12-04-2021

From P-1 to bridge the river
has shorten its course by
600 m since 2004

The closure of a number of meanders potentially
removed a reservoir volume of around 50-100,000 m³
for floods, sediment catchment resulting in increased
estuary sedimentation and village flooding

Water Quality Sampling

The physical water quality parameter results are given in the table below:

Table 2. Water Quality Results

| Parameters | Site 1 | Site 2 | Site 3 | Site 4 | National Standard |
|---------------------------|--------|--------|--------|--------|--------------------|
| Temperature 0° | 26.28 | 26.44 | 26.33 | 26.23 | <38 |
| pH | 8.52 | 7.96 | 7.96 | 6.72 | 6.0 – 8.5 |
| Conductivity mS/cm | 0.116 | 0.237 | 0.243 | 0.097 | 0.020 – 0.25 mS/cm |
| Turbidity NTU | 5 | 4 | 6 | 5 | 2 – 15 NTU |
| Dissolved oxygen mg/l | 10.20 | 18.13 | 8.62 | 15.20 | >6 |
| Total dissolved solid g/l | 0.275 | 0.154 | 0.158 | 0.060 | 1g/l |
| Oil and grease | none | none | none | none | |

The temperature of all four sites has similar range while the pH range has increased from site 4 to site 1 (6.72 to 8.52).

Table 4.2

Physico-chemical results

| Site | Sample no. | Date | Time | Gauge m | pH | Cond $\mu\text{S}/\text{cm}$ | Temp $^{\circ}\text{C}$ | DO mg/L | DO % saturation | Turb NTU | TSS mg/L | Comments |

IN CONCLUSION

For effective guidelines we need the support of all stakeholders but also a willingness to take ownership of the guidelines as well. In other words sharing responsibility and good stewardship for sustainable extraction of these resources.

For this to occur:

To strengthen the technical content of environmental impact assessment reports that provide sufficient data that can be used for MONITORING of the extraction and recovery of resources promoting sustainable exploitation.

Liaison and better co-operation within regulatory bodies

The private sector and the LOU communities working together to minimise illegal activity.

A goal to manage, protect, and restore the equilibrium condition of Fiji rivers to resolve or avoid conflicts between human investments and river dynamics in a manner that is technically sound, and both economically and ecologically sustainable.
